IGF 2018 Best Practice Forum on Internet of Things - Big Data - Artificial Intelligence

I. Introduction

1. The IGF BPF on IoT, Big Data, AI

One of the key outcomes of the World Summit for the Information Society (WSIS) was the Internet Governance Forum (IGF). The IGF is a global forum where governments, civil society, the technical community, academia, the private sector, and independent experts discuss Internet governance and policy issues.¹ The annual IGF meeting is organized by a Multistakeholder Advisory Group (MAG) under the auspices of the United Nations Department of Economic and Social Affairs (UN DESA). The 13th annual IGF meeting takes place in Paris, France, on 12-14 November 2018.

The IGF Best Practices Forums (BPFs) bring experts and stakeholders together to exchange and discuss best practices in addressing an Internet policy related issue in a collaborative, bottom-up process. BPFs prepare their work in a series of intersessional discussions and a workshop at the IGF's annual meeting. The activities of the BPFs culminate in an output document including an understanding of global good practice, that is intended to inform policy discussions, standards development, business decisions, as well as public understanding, awareness, and discourse.

2. Framing the work of the BPF IoT, Big Data, AI

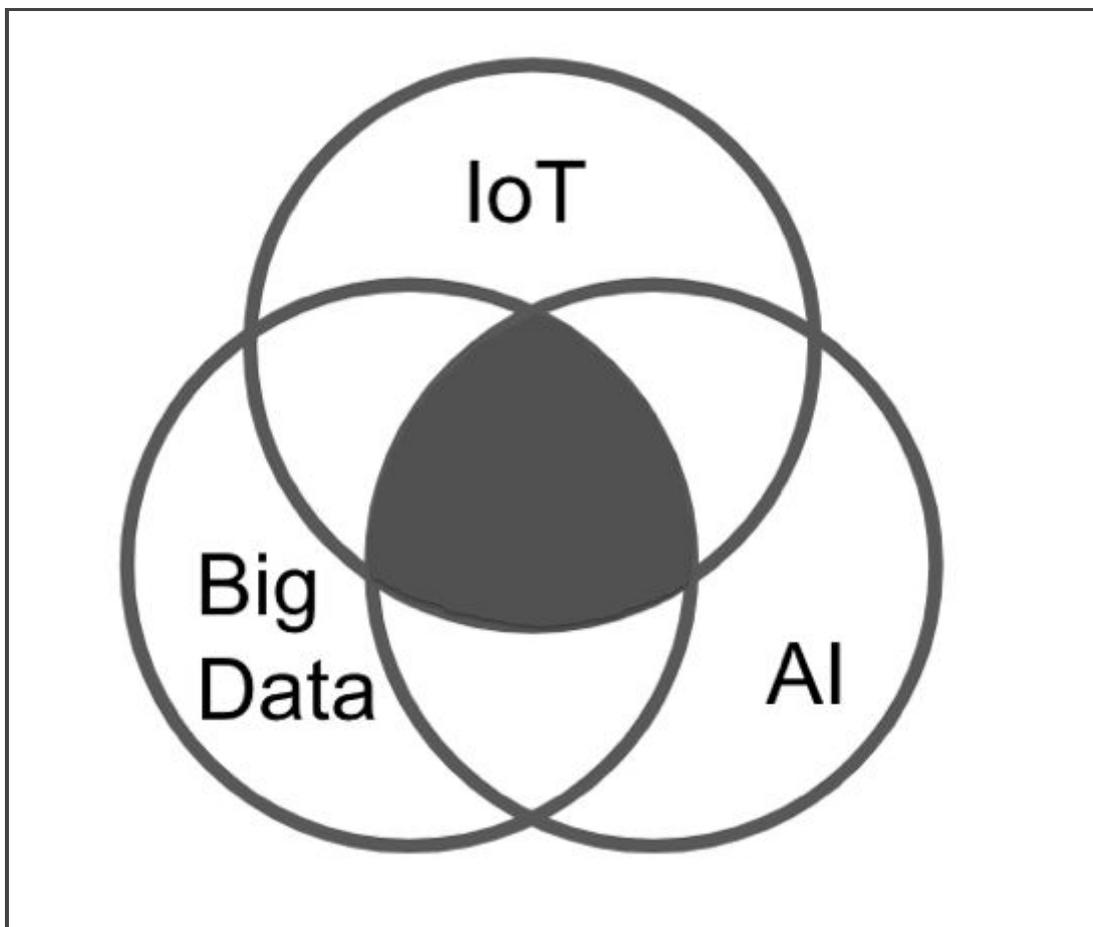

The BPF on the Internet of Things (IoT), Big Data and Artificial Intelligence (AI) aims to determine how combining these technologies can benefit Internet users and others around the world, and what is needed to ensure that the benefits do not come at the cost of trust in society at large because of increase in (justified) concerns about affecting privacy or

¹ IGF website: <http://www.intgovforum.org>

self-determination of people. It also examines how to address growing concerns about misuse and misunderstanding of emerging technologies.

Where IoT, Big Data, AI are being used in concert ...

Today IoT, Big Data, AI discussions are present in many fields, both in the on- and offline world. The BPF will focus on where these technologies meet in an Internet context, and how Internet governance can stimulate their development and widespread use, as well as help avoid unintended negative side-effects. Each of the three technologies are being used in many different ways in many different fields. The focus in this report is on where all three technologies are being used in concert. In other words, rather than try to cover all the issues in the entire Venn Diagram below, we will focus on the overlap in the middle. In this, we are aware that the overlap will grow, and the edges (where IoT is not relating to big data, or does not become part of AI applications) are blurry, at best

Focus of the BPF: where IoT, Big Data, AI are being used in concert.

While, already, there are multiple examples of benefits coming from IoT, Big Data and AI, the expectations about how these technologies will change our future are high: for example, by improving efficiency and cost saving, enabling better and more accurate decision-making and the discovery of specific data patterns, and complex cause and effect relationships, etc. IoT, Big Data, and AI can contribute to solving complex problems and facing global

challenges related to the environment, transportation, health, etc., and will help achieve SDGs in ways that otherwise may not even be possible. Also on the level of the individual internet user there is an almost endless and growing list of examples of how new technologies and applications could help support daily life.

While the new technologies have the ability to help to tackle many global challenges and support people in their daily pursuits, there are a large number of unknowns, potential impacts, risks, and social and economic implications related to privacy and discrimination, inequality and infringement of human rights, etc.

Stakeholder Dialogue

Stakeholder dialogue should play an important role in identifying risks and seeking ways to mitigate unwanted side-effects, to understand how the Internet can further develop embracing IoT, Big Data and AI to the benefit of all.

Stakeholder debate and dialogue is required to help stakeholders to select, adopt and develop the right measures and policies for managing the impact of these new technologies on the society.

When considering the combination of the Internet of Things, Big Data, and Artificial Intelligence, the number and type of key stakeholders is even larger and more varied than in the case of traditional Internet governance.

They include the following groups, which in themselves are spread across different industry sectors:

- Researchers who develop new techniques;
- Engineers and developers who create, improve, and deploy solutions;
- Standards experts who craft international standards to foster adoption;
- Marketing teams who define how applications will be sold;
- Lawyers--in both businesses and government--who apply laws to technology;
- Regulators who apply existing rules or draft new rules for new use cases;
- Government policy makers who set policy goals;
- Consumer advocates who spot abuses and fight for remedies; and
- Diplomats and international organizations working for global approaches.
- Internet users, who are affected by AI through its mediation of their daily communications and information consumption (such as through delivery of advertising, news, and social media content through algorithms and profiling) and role in automated decision-making.

Each stakeholder group offers a unique and important understanding of how these technologies impact daily life, and how policy can balance innovation with potential risk. And within those stakeholder groups, it is important to recognise that those who contribute, for instance, to aerospace industry, or those contributing to personal health, or to domotics, will have different emphasis in terms of concerns and aims. They should be encouraged to

collaborate as often as possible in order to manage the impact of these emerging technologies.

3. Objectives of the BPF output

The BPF document is intended to inform policy discussions, by describing different issues and reflecting on ongoing discussions in a format tailored to an audience of policy makers who do not necessarily deal with technology on a day-to-day basis.

The BPF aims to be a multi-stakeholder and multi-disciplinary platform to understand the wider context of IoT, Big Data, AI, for each stakeholder group, and discuss opportunities and threats related to the application of these technologies on the Internet, and ways to stimulate the positive or mitigate the negative, only then these new technologies can contribute to the benefit of all and support reaching the United Nations Sustainable Development Goals (SDGs).

The BPF identified a set of focus points for stakeholder discussion.

1. Explore the benefits and potential dangers of the use of IoT, Big Data, AI in an Internet context.
2. Identify existing platforms and communication mechanisms for stakeholder discussion on issues related to the use of IoT, Big Data, AI and the Internet;
3. Collect examples and good practices of how stakeholder cooperation can help to mediate common problems and issues and stimulate the use of IoT, Big Data, AI and the Internet to the benefit of all;
4. Identify how IoT, Big Data, AI can be used to reach the United Nations SDGs;
5. Identify the impacts on policies and regulations, policy making, of the application of IoT, Big Data, AI;
6. Start a discussion with stakeholders to highlight their roles and responsibilities and help focus attention on some of the most exciting opportunities and largest potential problems..

The 2018 BPF, as it is the first time a BPF is organised on these new technologies, is necessarily a fact finding exercise, and will focus on the first three points of the above list in order to start a discussion on a general principle on the use of these technologies to the benefit for all.

The 2018 BPF, as such, will be a sound basis for further discussion and strengthened stakeholder cooperation to stimulate the uptake and further development of these new technologies in such a way that they fully contribute to the benefit of all and the achievement of the SDGs.

4. Methodology and acknowledgements

This document reflects the work of the 2018 BPF on IoT, Big Data, AI . The BPF outcome document is the result of an open and iterative process during the months preceding the 2018 IGF meeting in Paris, France, 11-14 November 2018. The structure and the content of the document were developed through a series of open and collaborative discussions with interested stakeholders, on an open mailing list², virtual webex meetings³, and a BPF face-to-face meeting during the IGF in Paris. A short survey⁴ conducted in June/July on the BPF and IGF mailing list helped the BPF in identifying potential topics for a BPF on IoT, Big Data and AI, and identify platforms and working groups that are discussing or well-placed to discuss IoT, Big Data, AI issues.

II. An Introduction to IoT, Big Data, and AI

1. Introduction

Devices, networks and applications used by billions of users around the world generate a vast variety and high volume of data. Technologies such as IoT, Big Data and AI play a critical role in connecting, analysing, and generating value from this growing amount of information. In this document, those technologies are therefore considered as a technological ecosystem where security, governance and ethics support the development of innovative services and applications impacting end-users daily life.

Thanks to the availability of big data and cloud computing, main players like Google, Facebook, and Amazon can classify and group user data by means of machine learning applications, to extract user profiles and models and apply them in a variety of contexts. Millions of images collected by online applications can be compiled and analyzed then used to “train” machine learning algorithms needed in fields as diverse as retail, security, and health care. Self-learning algorithms are also available on our mobile devices, influencing our choices, our purchases, and our behaviour, among other things. CDN companies such as Akamai and Cloudflare handle trillions of Web requests each day and apply machine learning to detect and block malicious attacks. Such algorithms also affect the news we consume through our social media feeds. Many of these algorithms work by collecting our personal information in order to make decisions about what to offer us.

The Internet of Things (IoT), as well as increasing the permeation of the internet into more aspects of our lives; provides an interface to feed data to, and receive data from AI in the cloud. Smart sensors distributed to several objects collect can distribute a huge amount of data over the Cloud. IoT devices generate a huge amount of data essential for much contemporary AI and big data.

2. Definitions

2.1. Internet of Things

While there is no universal definition, the Internet of Things (IoT) typically refers to “scenarios where network connectivity and computing capability extends to objects, sensors and everyday items not normally considered computers, allowing these devices to generate,

exchange and consume data with minimal human intervention”⁵. Well known to the public are consumer IoT devices. They include everything from toasters, fridges and vacuum cleaners, to personal assistants and fitness coaches. They unlock our homes and keep the temperature inside regulated. They exist in our cars and our toothbrushes and our watches, and the use cases are only growing. There’s also a vast amount of examples of IoT making an introduction in the public space and industrial IoT applications.

It is projected that IoT devices will number 38.5 billion in 2020, up from 13.4 billion in the year 2015⁶.

While much public attention has been paid to consumer applications of the IoT, many of the most important and beneficial uses will be elsewhere.

Some existing and potential use cases that combine the IoT with Big Data and Artificial Intelligence include:

- Sensors for monitoring infrastructure (bridges, roads, sewers, water systems);
- Factory automation;
- Logistics and supply chain management;
- Medical treatment and home health care;
- Emergency warning systems;
- Crop optimization systems;
- Home security and crime prevention; and
- Personal health monitors.

When discussing the Internet of Things, it is critical to understand that the Internet has become more than just a communications network. It has become a computing platform as well. The simple model of the IoT where a device reports back to a single server has been replaced with an Internet architecture that includes secure gateways for protecting and managing the devices, Content Distribution Networks (often consisting of hundreds or even thousands of servers) that collect and cache data, layers of security, cloud computing data centers, and a range of edge computing services. For this reason it might make sense to refer to a “Cloud of Things,” because that make clear that telecommunications networks are just part of the infrastructure that enables the IoT.

2.2. Big Data

Big Data can be defined as a set of data-processing applications, codes and platforms created to analyse high volumes, velocity and variety of data. Generating insights from complex and unstructured data sets, Big Data enables developers, businesses and governments to better scope and anticipate user experience and context of usage. As a

⁵ <https://www.internetsociety.org/resources/doc/2015/iot-overview>

⁶

<https://www.juniperresearch.com/press/press-releases/iot-connected-devices-to-triple-to-38-bn-by-2020>

supporting activity, data science provides standardized tools and methodologies to develop complex algorithms able to process and analyse such data streams.

While researchers and companies have been using computers to collect and analyze “Big Data” for more than five decades, the Internet of Things has fundamentally “changed the game.” What’s exciting about today’s Big Data applications is that the amount of data being collected is not just massive--it’s also changing rapidly: it is coming from widely-distributed locations (many of which are moving); it may come from a range of types of sensors; and it may be unstructured, messy, and full of noise or errors. The ability to collect and analyze data not only from sensors (like temperature or location) but also on the tone and emotional content of a tweet, an customer complaint, or a corporate email, could lead to unexpected insights and process improvements.

Source: <https://marketoonist.com/2014/01/big-data.html>

2.3. Artificial Intelligence

Artificial Intelligence refers to a set of theories, methodologies, approaches and practices that give computers or computing systems the ability to perform tasks that are associated with humans (intelligent beings). AI has been with us for over sixty years, and there are a number of theories and approaches that are included in the general discussion of AI; such as Machine Learning (ML) and Deep Learning (DL). Most of artificial intelligence used in

practice and focused on by researchers and developers focuses on giving computers tasks commonly performed by humans. Some AI theory and practices focuses on creating computer systems that can learn and think like humans, and thus modelled on the way human beings reason, more like the AI we know from science fiction such AI, called “strong AI”⁷ represents a minority of contemporary AI, although remains a focus of AI in media and contemporary discourse.

Source: cubicsol.com/deep-learning-machine-learning-ai/

The AI category includes sub fields that are sometimes discussed separately such as knowledge engineering and machine learning.

“AI traditionally refers to an artificial creation of human-like intelligence that can learn, reason, plan, perceive, or process natural language. These traits allow AI to bring immense socioeconomic opportunities, while also posing ethical and socio-economic challenges.” (From Internet Society’s AI/ML Policy Paper)

Machine learning is a particular approach to AI, and one of the most widely-used AI-related technologies used on the internet.

“Instead of programming the computer every step of the way, machine learning makes use of learning algorithms that make inferences from data to learn new tasks.” (From Internet Society’s AI/ML Policy Paper)

AI is already being used for tasks that many users may not be aware of, including email filtering, content personalization (such as Netflix recommendations), fraud detection, and speech recognition (such as Alexa and Siri). As the technology continues to develop and expand its applicability, users will likely interact with AI systems in greater capacities.

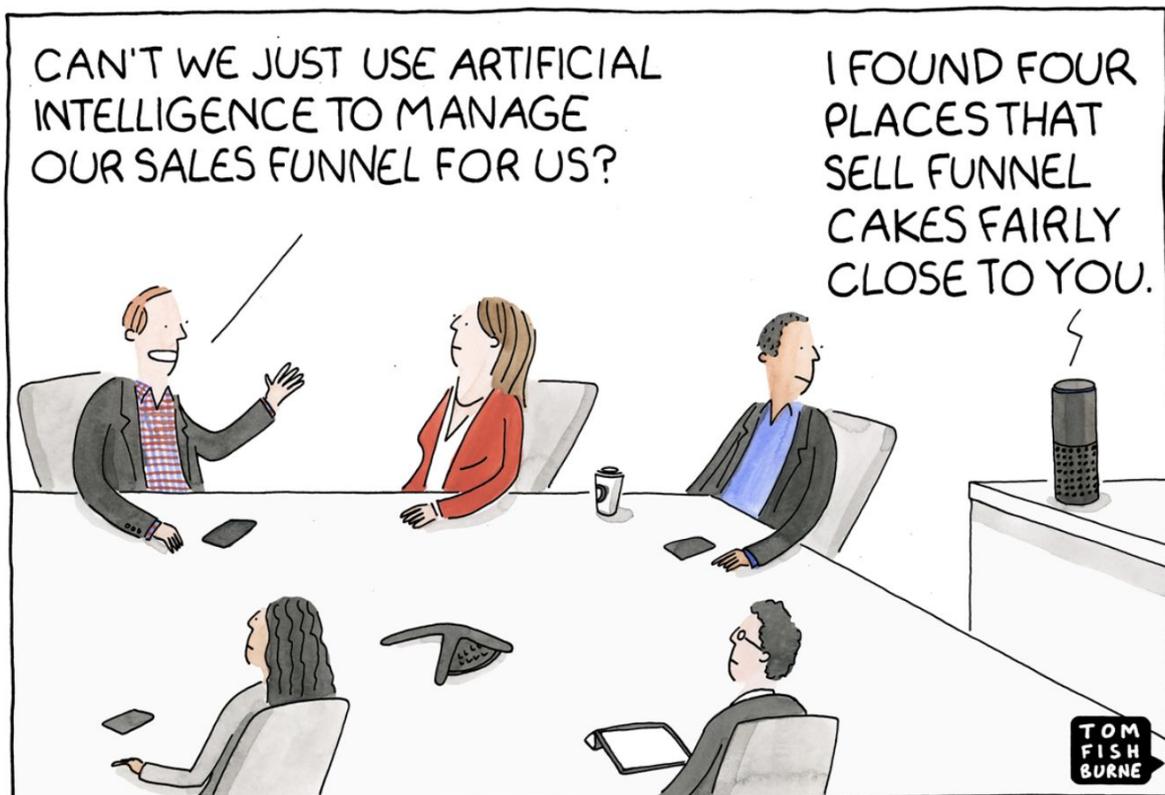

There is a great deal of confusion about Artificial Intelligence, in part due to confusion⁸ about the term, which has been in use since at least 1956⁹. Since then it has been defined in many, conflicting ways.

⁷ Searle, John R. "Minds, brains, and programs." Behavioral and brain sciences 3.3 (1980): 417-424. cogprints.org/7150/1/10.1.1.83.5248.pdf

⁸ For some useful cartoon examples: <https://marketoonist.com/2017/09/ai.html>

⁹ http://agisi.org/doc/AGISI_DefinitionsIntelligence.pdf

At various times, “Artificial Intelligence” has been applied to almost every type of algorithm: Voice recognition systems; Image recognition systems; Decision support software; Factory robots; Machine learning; Autonomous vehicles (e.g. self-driving cars and drones); Cognitive computing; and MUCH more. Because of the exciting (and confusion) around the terms “artificial intelligence” and “machine learning” almost anything digital is being labelled “AI” or “machine learning.” Indeed, the famous Gartner hype curve showed machine learning reaching peak hype in 2016¹⁰.

Source: <https://marketoonist.com/2017/09/ai.html>

2.4. How IoT, Big Data and AI come together

As the pervasiveness of IoT devices increases, so too does the likelihood that consumers will interact with dozens or even hundreds of IoT devices. Each of their devices collects huge amounts of data about their daily activities. Everything from heart rate, daily movements and routines, and even the layout of users homes can be tracked. This data is often compiled, sold, and used in very different ways than users may expect. This creates a perfect environment for new AI applications and services, which rely on big data, to grow and

¹⁰ <https://contently.com/2017/05/23/artificial-intelligence-hype-cycle-5-stats/>

evolve. As users adopt more IoT devices into their lives they are, often unknowingly, contributing data to future applications of AI and machine learning.

A practical example where the three technologies are used in synergy are Smart Cities, where through IoT devices you can harvest vast amount of datas that through AI could be used to develop predictive models to manage critical services such as public transportation, pollution monitoring, garbage collection, and others.

These are powerful technologies--and when combined they become even more powerful tools, which can be used for good or evil. The BPF working group had extensive discussions about how IoT, Big Data and AI could be developed and used in ways that reflect ethical considerations and human rights.

2.5. Proposed Best Practices (regarding definitions)

#1 - Define your terms narrowly

The fact that the term “Artificial Intelligence” and “Internet of Things” has and can be used in so many ways make it essential that policy makers, business leaders, non-governmental organizations, and users of technology make clear what aspect of these technologies they are discussing. Not doing so can lead to sweeping generalizations or proposals meant to address a problem with a narrow technology or specific application that could have a range of unintended consequences. Worse, by conflating dozens of different technologies and hundreds of different applications into one conversation it is likely that the “fear factor” caused by science fiction depictions of SkyNet and other AI scenarios will cause discussions to lose focus.

#2 - Be ecumenical about technology (or “Strive to be technology-neutral”)

Because technologies are changing so quickly and because potential problems with a specific applications may or may not develop (or may be solved rapidly), it is dangerous and unproductive to try to write laws and regulations that cover one specific type of technology or one specific type of application. Best practice is usually to focus on what an application DOES not on how the technology DOES IT.

III. The key role of Internet Governance

1. Internet Governance Challenges

- **IoT Cybersecurity**

IoT devices can be used to form botnets -- “networks of Internet-connected externally controlled devices”

[\[https://www.internetsociety.org/resources/2018/iot-security-for-policymakers/\]](https://www.internetsociety.org/resources/2018/iot-security-for-policymakers/). Once infected with malicious software, the devices and everything they are connected to can be compromised. The devices can be used to “infect” and disrupt entire networks, other users, and the Internet infrastructure at large. The 2016 botnet attack against Dyn, a DDoS attack that made thousands of major websites temporarily inaccessible, used IoT devices to facilitate the attack [\[https://www.internetsociety.org/blog/2016/10/trust-isnt-easy-drawing-an-agenda-from-fridays-ddos-attack-and-the-internet-of-things/\]](https://www.internetsociety.org/blog/2016/10/trust-isnt-easy-drawing-an-agenda-from-fridays-ddos-attack-and-the-internet-of-things/).

It is critically important that IoT device developers consider security at the earliest stages of development, i. E. implementing the principle of security / safety by design. But it is equally important that users understand what is at risk and what they can do to protect themselves and others from attacks through IoT devices. It will take mass education of developers, consumers, policy makers, and vendors to ensure that the Internet is protected from IoT attacks. Groups such as the Internet Society and Consumers International are already working together to ensure industry and consumer groups improve the overall security and privacy of IoT offerings, and to make sure consumers have products or services that are secure and privacy-respecting

[\[https://www.internetsociety.org/blog/2018/06/a-partnership-to-tackle-growing-risks-in-a-connected-world/\]](https://www.internetsociety.org/blog/2018/06/a-partnership-to-tackle-growing-risks-in-a-connected-world/). The IGF is another excellent forum for stakeholders from all over the world work together to secure IoT before another mass botnet attack is launched.

- **AI mass data processing**

Some AI techniques, like machine learning, make use of massive amounts of data to train the system in producing significant answers and decisions. This creates three problems:

“**Data dominance**”. Refers to the phenomenon where big companies like Google or Facebook (or large countries¹¹) gather massive amounts of data, giving them an advantage over smaller competitors in the AI field.¹²

11

<https://foreignpolicy.com/2017/09/08/china-is-using-americas-own-plan-to-dominate-the-future-of-artificial-intelligence/> and <https://www.newamerica.org/cybersecurity-initiative/blog/chinas-plan-lead-ai-purpose-prospects-and-problems/>

¹² <https://www.datasciencecentral.com/profiles/blogs/what-makes-a-successful-ai-company>

Data bias. The problem of the quality of the datasets used to train the system: if data are incomplete, inaccurate, or reflect social inequalities, the answers and decisions taken by an AI application might be incomplete, inaccurate, flawed or discriminatory. Therefore accurate information needs to be fed into the system.

Ethical Decision Making. AI systems are wired to output the most logical solution to problems, but those solutions may not always be the most ethical. It is critical that programmers build ethical considerations into AI algorithms.

(example: BBC video AI & ethics - self driving car:

<https://www.facebook.com/bbc/videos/2095617507120104/>)

Anonymization. A privacy related issue: data used to train the systems must be rendered anonymous for preserving the privacy of users, but if too much information is omitted the data might be useless, so investigating the right tradeoff is important. Another issue lies in de-anonymization strategies used to re-identify users.

Transparency. AI systems can output solutions without clear justification, or understanding, of how and why it reached that conclusion. Consumers may not have any knowledge about why a system is interacting with them in a certain way. For this reason, developers must be as transparent as possible about how their algorithms are built. This will allow the public to serve as a check on any AI system making “bad” or wrong decisions.

- **AI threats to human rights, security, and social cohesion**

AI can pose threats to human rights, security, and social cohesion. There is the legal issue of whom to consider liable for the errors or shortcomings of an outcome where an AI is used. Another concern is about improper use of AI: it might be easier to forge audio and video media and spread fake news; AI can guess more accurately an individual's tastes thus exacerbate filter bubbles; and new cyber attacks involving AI could be deployed.

Another crucial aspect is **intelligibility**: in some AI technologies like deep-learning, there is such a level of complexity that it is not possible even for their developers to know why and how the AI has come to the final answers or decisions. But this can create a huge problem when an AI is used to make decisions or get answers in critical situations where the outcome has a great impact on an individual's life, thus it's important to identify these situations and restrict the use of unintelligible AI's technologies in these scenarios. Therefore the EU GDPR regulates decision making based solely on AI in Art. 22 (1) as follows: “The data subject shall have the right not to be subject to a decision based solely on automated processing, including profiling, which produces legal effects concerning him or her or similarly significantly affects him or her.”

Moreover AI technologies can have a dramatic impact on the labour market: they can increase productivity, reduce costs, and create new jobs; but they can also replace old ones, create new inequalities, and bring a decrease in wealth distribution. It is

crucial to understand how and which jobs are automatable, and on what extent AI can replace human labour. It is important to discuss retraining programs to enable workers to enter new careers or to be able to fully exploit this new technology.

- **Positive Impact on economies and Innovation**

AI depends on Big Data to function. As the demand for “intelligent” technologies increases, so too will the demand for data. This may incentivize companies to collect more data about users, raising the risk of oversharing user information at the expense of privacy and security.

2. Proposed Best Practices (regarding uses of IoT, Big Data, and AI)

#3 - Collaborate

It is critical that government officials, technologists, civil society, academics, and others work together to ensure that these technologies are deployed in ways that protect user privacy and security, and network resiliency while fostering innovation. Stakeholders should communicate openly about the impact new technologies have on the public and existing networks and find ways to work together to develop future-looking policies.

#4 - Consider ethics and human rights when applying IoT, Big Data, and AI

The people developing and deploying systems, products, and services that leverage IoT, Big Data and AI should take ethical considerations and human rights into account from the outset—in the development, deployment and use phases of the life cycle. This requires that users are aware of the benefits and risks deriving from these technologies

#5 - Watch out for bias and incomplete data sets

Users of IoT data must realize that the data they collect may reflect only a small subset of the “real world.” This may be due to the Digital Divide. It might be due to national regulations that restrict the export of consumer data. It might be due to marketing decisions to only focus on certain geographies, demographics, or industry sectors. In some cases, statistical techniques can weight data to compensate for some problems. But in ALL cases, companies and governments should recognize the limits of the data and Big Data analysis. The Obama Administration released two very important reports¹³ that addressed “data discrimination” and provided useful recommendations.

#6 - Make privacy and transparency a policy goal and a business practice

In a sector evolving as rapidly as the Internet of Things, it is important that potential problems be recognized before they become serious. Companies that develop new applications that collect and use data without informing their customers (or do not reveal all the ways in which they are using their data) often face a serious loss of reputation and trust when their

13

<https://obamawhitehouse.archives.gov/blog/2016/05/04/big-risks-big-opportunities-intersection-big-data-and-civil-rights>

business practices are revealed (usually by outside researchers or by current or former employees). More and more Internet companies are publishing transparency reports and such reports are likely to become more common and more detailed as the IoT enables data collection about more intimate aspects of our lives. Transparency is one of the most effective ways for companies to nurture trust.

#7 - Ensure systems are adequately secured before they get to the market

Over time, and leading to a very high level pace of innovation, industry has been led by a drive of shortest possible “time to market”. Whereas this has led to high pace of innovation, this has also led to failures of systems, and flaws in systems that will still haunt us in the years to come, as long as those systems with inherent flaws are in use within our networks. By making industry responsible for system failures and vulnerabilities, the price of such failures and vulnerabilities are likely to become more explicitly more part of the consumer price of the products. In many ways this is comparable to invoking a “taxation” on eco impact of household appliances, etc. A balance will need to be found to distinguish “flaws resulting from irresponsible behavior” to flaws that could not be foreseen at the time, whereas system development has followed good practice - industry self-regulation may be the best way forward as to avoid regulation that is stalling innovation.

#8 - Foster technologies and business practices that empower SMEs

There is a common assumption that the biggest companies will be the biggest winners when it comes to the IoT, Big Data, and AI. Yet, already companies like IBM are building systems that enable the smallest companies to apply leading-edge solutions to their problems. The growth of edge computing¹⁴ and “serverless computing” promises to give SMEs much cheaper and simpler ways to create the software needed to exploit the power of the data generated by the Internet of Things. The best response to the threat of “Data Dominance” is not regulating monopolies, it is ensuring there are not monopolies by ensuring vibrant competition.

3. role of Internet Governance with regard to IoT/Big Data/AI

Why do these technologies matter to IG?

Key role of Internet Governance with regard to IoT/Big Data/AI

- Stimulate the development of new applications of these technologies on and using the Internet, to the benefit of all;
- Provide ways to highlight and disseminate information about new tools and applications;
- Avoid risks and threats emerging from the further developing use of these technologies;

14

<https://www.economist.com/business/2018/01/18/the-era-of-the-clouds-total-dominance-is-drawing-to-a-close>

- Make sure that business or government practices do not slow down the development and new applications of which all can benefit;
- Caution towards decision making based solely on AI and machine learning (ref. to GDPR recital 71);
- Provide ethical guidance with regards to health, defense, cybersecurity and privacy usage;
- Facilitate access to skills and knowledge, inclusion;
- Facilitate conversations among relevant stakeholders, including creators of new technologies and users, to discuss ways to balance innovation and potential risk through policymaking.

From G20 Digital Economy Ministerial Declaration (Aug 2018)¹⁵

We encourage countries to enable individuals and businesses to benefit from digitalization and emerging technologies, such as 5G, Internet of Things (IoT), artificial intelligence (AI), distributed ledger technologies, by: i) considering appropriate policy approaches and flexible legal frameworks that create an environment that empowers entrepreneurs and fosters research, innovation and competition; ii) promoting the application of emerging digital technologies in manufacturing, agriculture and other vital areas; and iii) We face the challenge of capturing the benefits of digitalization to improve productivity that may lead to new business models including sharing economy, economic development, and the realization of broader taking into account the challenges that these new technologies may pose in terms of privacy and security, among others, and the opportunities to improve quality of life and foster economic growth.

V. Next Steps ?

[Possible next steps for a BPF on IoT, Big Data, and Artificial Intelligence will be discussed in sessions at the IGF in Paris. This section will be drafted after the IGF based on that discussion.]
